Meta-regression analysis (MRA) is a quantitative method of conducting literature surveys. Meta-regression has gained popularity in social, behavioral and economic sciences. Important applications have focused on qualifying estimates of policy-relevant parameters, testing economic theories, explaining heterogeneity, and qualifying potential biases.

In primary studies we use regression, or multiple regression, to assess the relationship between one or more covariates (moderators) and a dependent variable. Essentially the same approach can be used with meta-analysis, except that the covariates are at the level of the study rather than the level of the subject, and

Meta-Regression

Conceptually, Meta-Regression does not differ much from a subgroup analysis. In fact, subgroup analyses with more than two groups are nothing more than a meta-regression with categorical predictors. However, meta-regression does also allow us to use continuous data as predictors and check whether these variables are associated with effect size differences.

Version 3 includes a new module for meta-regression that. Allows you to include any number of covariates. Allows you to define sets of covariates. Allow you to include both categorical and

continuous covariates in the model. Will automatically create dummy variables for categorical covariates. Allows you to define and compare multiple predictive models.

What's New in Version 3? | Comprehensive Meta-Analysis

- Meta-regression is a statistical technique used in a meta - analysis to examine how characteristics of studies are related to variation in effect sizes across studies
- Meta-regression is analogous to regression analysis but using effect sizes as our outcomes, and information extracted from studies as moderators/predictors

8.2 Plotting Regressions | Doing Meta-Analysis in R

In meta-regression, our sample of data is mostly small, as we can only use the synthesized data of all analyzed studies k . As our meta-analysis aims to be a comprehensive overview of all evidence, we have no additional data on which we can “test” how well our regression model can predict high

or low effect sizes.

The `regtest.rma` function can be used to carry out various versions of the regression test. The model is chosen via the `model` argument, with `model="lm"` for weighted regression with a multiplicative dispersion term or `model="rma"` for the meta-analytic models.

Meta-regression. The results from the full model meta-regressions are presented in table 1. When combined, baseline protein intake, protein dose, age and training status did not explain any of the variance in the changes in 1RM (15 studies, 1216 subjects, $p=0.77$) or FFM (15 studies, 642 participants, $p=0.12$).
